### Abstract

**Background:** TCR and CXCR4-mediated signaling appears to be reciprocally regulated pathways. TCR activation dampens the chemotactic response towards the CXCR4 ligand CXCL12, while T cells exposed to CXCL12 are less prone to subsequent TCR-activation. The heterotrimeric G proteins  $G_{\alpha q}$  and  $G_{\alpha i2}$  have been implicated in CXCR4-signaling and we have recently also reported the possible involvement of  $G_{\alpha q}$  in TCR-dependent activation of Lck (Ngai et al., Eur. J. Immunol., 2008, 38: 32083218). Here we examined the role of  $G_{\alpha q}$  in migration and TCR activation.

**Results:** Pre-treatment of T cells with CXCL12 led to significantly reduced Lck Y394 phosphorylation upon TCR triggering indicating heterologous desensitization. We show that knockdown of  $G_{\alpha q}$  significantly enhanced basal migration in T cells and reduced CXCL12-induced SHP-1 phosphorylation whereas  $G_{\alpha i2}$  knockdown inhibited CXCL12-induced migration.

**Conclusion:** Our data suggest that  $G_{\alpha i2}$  confers migration signals in the presence of CXCL12 whereas  $G_{\alpha q}$  exerts a tonic inhibition on both basal and stimulated migrational responses. This is compatible with the notion that the level of  $G_{\alpha q}$  activation contributes to determining the commitment of the T cell either to migration or activation through the TCR.

### Background

Chemokines dictate the migration and positioning of leukocytes at steady-state and in inflammation [1]. The chemokine CXCL12, also known as stromal cell-derived factor-1 $\alpha$  (SDF-1 $\alpha$ ), is a member of the CXC chemokine subfamily and serves as the only known ligand for the chemokine receptor CXCR4 expressed on most leukocytes [1-3]. Mice lacking CXCL12 or CXCR4 die perinatally of cardiovascular, neurologic, vascular, and hematopoietic defects [4,5]

The CXCR4 receptor is a G-protein coupled receptor (GPCR) and couples to heterotrimeric G-proteins of both the  $G_{\alpha i}$  and  $G_{\alpha q}$ -families [6-8]. Members of the  $G_{\alpha i}$ -family of G-proteins are pertussis toxin sensitive and pre-treatment of cells with pertussis toxin severely attenuates chemotaxis in response to chemokines.  $G_{\alpha i}$ -proteins are therefore thought to be essential for chemokine-mediated migration. Of the  $G_{\alpha i}$ -family,  $G_{\alpha i2}$  and  $G_{\alpha i3}$  are strongly expressed by lymphocytes [9].  $G_{\alpha i3}^{-/-}$  mice are without phenotype [10] whereas  $G_{\alpha i2}^{-/-}$  mice display dysfunctional

T cell functions as well as defective chemotaxis in response to chemokines [6]. In contrast,  $G_{\alpha_q}$  has been shown to be required for chemotaxis of dendritic cells and granulocytes, but not for T cells [7].

Stimulation of the T cell receptor (TCR), the B cell receptor, or the Ly49D activating receptor all reduce lymphocyte migration toward CXCL12 [11-14] suggesting that cells dedicated to proliferation/differentiation are less sensitive towards chemokines. The opposite is also true, as cells exposed to CXCL12 show less phosphorylation of ZAP-70 and LAT following subsequent TCR activation indicating reciprocal regulation between CXCR4 and the TCR [13]. In addition, recruitment of chemokine receptors into the immunological synapse has been shown to stabilize T cell-APC interaction through activation of a  $G_{\alpha_q}$ -dependent pathway. This renders the cell less responsive to chemotactic gradients and gives higher T cell proliferative responses and cytokine production [8]. Recently, the TCR and CXCR4 were shown to closely associate upon CXCL12-stimulation [15], and it was suggested that CXCR4 signaling occurs through the immunoreceptor tyrosine-based activation motif (ITAM)-domain present in the CD3 $\zeta$  chain. Collectively, these results point to a direct crosstalk between the signaling machineries utilized by the TCR and CXCR4.

We have recently shown that  $G_{\alpha_q}$  knockdown in T cells inhibits the activation of the Src family kinase Lck [16]. The effect of  $G_{\alpha_q}$  on Lck activation might be conferred by a direct interaction and/or by affecting the threshold for TCR-triggering. We demonstrate here that knockdown of  $G_{\alpha_q}$  significantly enhances basal T cell migration while inhibiting TCR-induced Lck activation. Pre-treating cells with CXCL12 prior to stimulation with anti-CD3 leads to a similar inhibition of Lck activation indicating that cells directed to migrate are less responsive to TCR triggering. The signals conveyed by  $G_{\alpha_q}$  appear to be mediated through a SHP-1 pathway. Our data suggest that optimal TCR activation requires signaling through  $G_{\alpha_q}$  and that removal of  $G_{\alpha_q}$  locks the cell in migration modus making the cell less responsive to TCR signaling

## Methods

### Antibodies and reagents

Human recombinant CXCL12 was obtained from Invitrogen (cat. no. PHC1344) and Peprotech (Rocky Hill, NJ). Antibody to  $G_{\alpha_{i2}}$  was from Calbiochem (cat. no. 371727). Antibodies against SH-PTP1,  $G_{\alpha_q}$ , Lck, Protein A/G Plus Agarose beads and SH-PTP1 conjugated agarose beads were purchased from Santa Cruz (cat. no. sc-287, cat. no. sc-393, cat. no. sc-433, cat. no. sc-2003, cat. no. sc-287 AC). Antibodies against phospho-p44/42 MAPK (Thr202/Tyr204) and Src pY416 (detecting also Lck pY394) were obtained from Cell Signaling (cat. no. 9106 and cat. no.

2101). Anti-phosphotyrosine mAb (4G10) was purchased from Upstate (cat. no. 05-777). Peroxidase-conjugated secondary antibodies and Affinipure F(ab')<sub>2</sub> fragment Goat Anti-Mouse IgG were obtained from Jackson ImmunoResearch Laboratories (cat. no. 111-035-144, cat. no. 115-035-146, cat. no. 115-006-072). Anti-CXCR4-PE was obtained from BD Pharmingen (cat. no. 555974).

### siRNA design

21-nt siRNA duplexes targeting human  $G_{\alpha_q}$  mRNA (NM\_002072) (GNAQ-1103; 5'-GGAGUACAAUCUG-GUCUAAUU-3'; 5'-UUAGACCAGAUUGUACUCCUU-3') and a triple G/C switch control (GNAQ-1103M3; 5'-GCA-GUAGAAUCUGCUCUAAUU-3'; 5'-UUACACCACAUU-GUAGUCCUU-3');  $G_{\alpha_{i2}}$  mRNA (NM\_002070.1) (GNAI-1050; 5'-GGACCUGAAUAAGCGCAAAGA-3'; 5'-UUUUGCGCUUAUUCAGGUCCUC-3') were designed and synthesized in-house. The oligos are named according to the position of the 5' nucleotide of the sense strand relative to the reference sequences. For a detailed characterization of the effect of these siRNAs, see Ngai et al. [16].

### Cell culture and transfections

The Jurkat TAG T cell line stably transfected with SV40 large T antigen was kept in logarithmic growth in RPMI-1640 (Invitrogen) supplemented with 10% FCS, 1% Penicillin-Streptomycin, 1% Non-essential amino acids and 1% Sodium Pyruvate.  $20 \times 10^6$  cells were washed and resuspended in 400  $\mu$ l OptiMEM (Invitrogen), mixed with cDNA or siRNA and electroporated in 0.4 cm electroporation cuvettes (Bio-Rad) at 250 V/cm and 975  $\mu$ F. Cells were harvested 48 hours post transfection.

### Cell stimulation and lysis

Cells were resuspended in RPMI 1640 to  $50 \times 10^6$ /ml and pre-incubated at 37°C for 5 minutes. Cells were then stimulated with 100 ng/ml CXCL12 or 1.5  $\mu$ g/ml OKT3 for the indicated time points and the reaction was subsequently stopped by lysis in ice cold lysis buffer (50 mM HEPES, 100 mM NaCl, 5 mM EDTA, 50 mM NaF, 10 mM Na-pyrophosphate, 1 mM Na<sub>3</sub>VO<sub>4</sub>, 1 mM PMSF, 1.0% Triton X-100). Where indicated, cells were pre-treated with 100 ng/ml CXCL12 or 10  $\mu$ M PP2 for 30 minutes at 37°C prior to stimulation. Samples were spun down at 13 000 rpm for 10 min and the supernatant boiled with SDS-buffer, subjected to SDS-PAGE and transferred to PVDF filters. Filters were subjected to immunoblotting with the indicated antibody over night at 4°C, washed  $3 \times 10$  minutes with TBS-T, incubated 45 minutes with secondary antibody at RT, washed  $3 \times 10$  minutes with TBS-T before incubation with SuperSignal West Pico Chemiluminescent Substrate for 5 minutes.

### Intracellular $Ca^{2+}$ measurement

Cells were resuspended to  $10^7$  cells/ml in PBS w/1% BSA and incubated with 4  $\mu$ g/ml Fluo-4 AM and 10  $\mu$ g/ml Fura Red AM for 30 minutes at 30°C. Cells were spun down and resuspended to  $3 \times 10^7$  cells/ml in PBS w/1% BSA. Cells were stimulated with 100 ng/ml CXCL12 and  $Ca^{2+}$  levels were measured by flow cytometry.

### Migration assay

Migration assays were performed in 24-well plates with 5.0  $\mu$ m pore-sized polycarbonate membrane inserts (Costar Transwell, Cat. no. CLS-3421). Cells were washed in RPMI-1640 supplemented with 2% FCS and 25 mM Hepes (chemotaxis medium) and resuspended to  $1 \times 10^6$  cells/ml. Six hundred  $\mu$ l chemotaxis medium was added to wells with or without 10 ng/ml CXCL12. Cells ( $1.5 \times 10^5$ ) were loaded into the transwell inserts and allowed to migrate for 2 hrs at 37°C and 5%  $CO_2$ . Cells that had passed through the filter into the lower chamber were collected and 10  $\mu$ l of an internal bead control (Bangs Laboratories, Fishers, IN) was added. The cells were counted by flow cytometry (FACS Calibur, Becton Dickinson) and normalized with reference to the internal bead control. Migration index was calculated as the number of cells migrating towards CXCL12 in the test well relative to the number of unmanipulated cells migrating towards medium in the control wells.

### CXCR4 surface expression

Forty-eight hours post-transfection, Jurkat T cells were stimulated with 100 ng/ml CXCL12 for different time points, washed in ice-cold PBS, fixed in 4% paraformaldehyde for 10 minutes at 37°C, washed in PBS, and resuspended in PBS w/1% BSA and anti-CXCR4-PE for 30 min at 4°C. Thereafter the cells were washed in PBS w/1% BSA and subjected to flow cytometric analysis for detection of surface CXCR4 expression.

### Statistical analysis

All data are representative of at least three different experiments. Values are expressed as mean  $\pm$  S.E.M as indicated in the figures. Statistical analysis was performed with Student's *t*-test.

## Results and Discussion

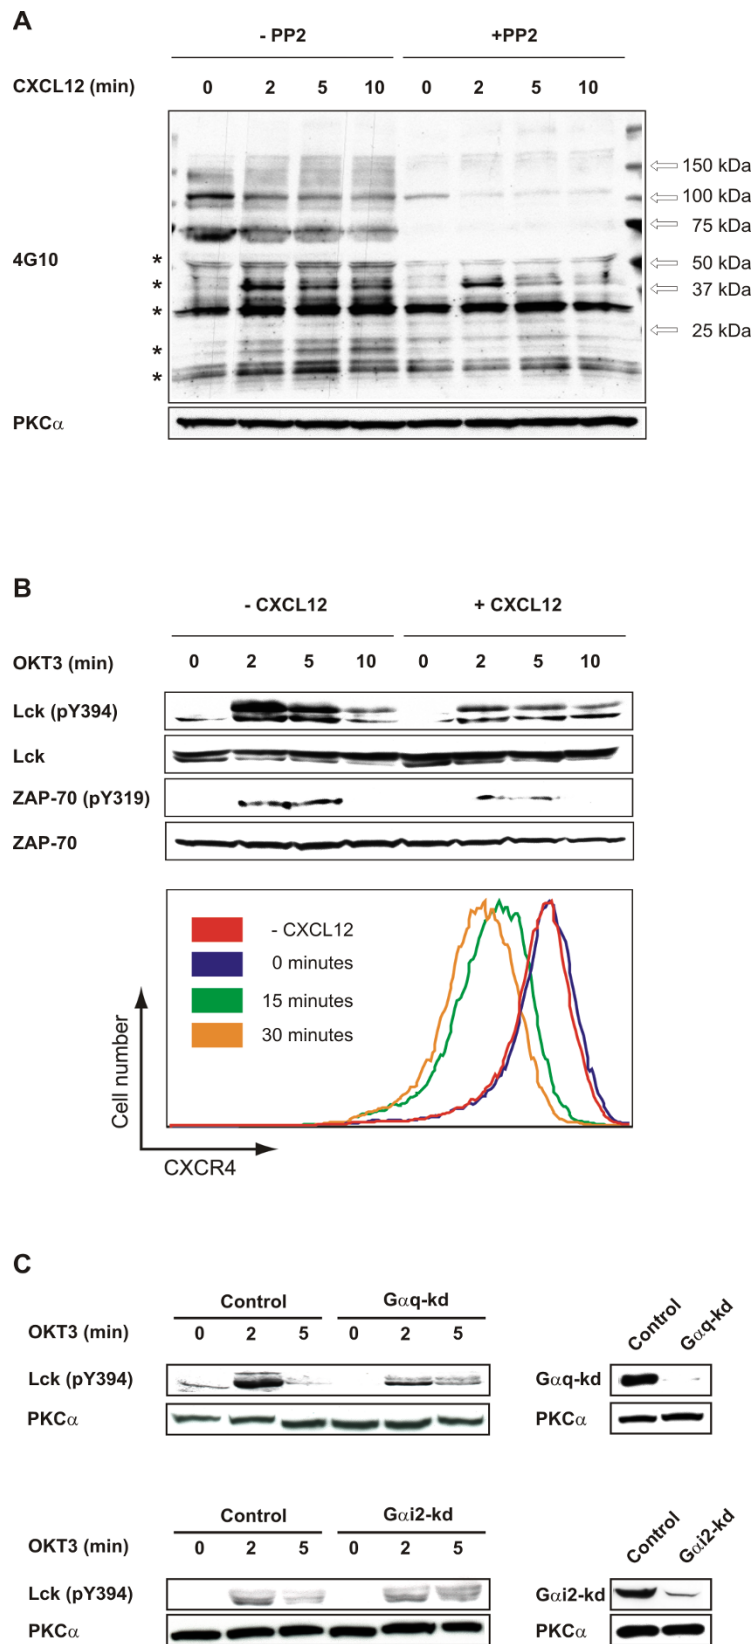

### CXCL12-pretreatment attenuates TCR-induced Lck activation comparable to the $G_{\alpha q}$ -kd-kd phenotype

We have previously shown that siRNA-mediated knockdown of the heterotrimeric G protein  $G_{\alpha q}$  in T cells attenuates TCR-induced Lck activation [16]. While the TCR is not thought to be directly associated with G proteins, the chemokine receptor CXCR4 can couple to both  $G_{\alpha q}$  and  $G_{\alpha i2}$ . Furthermore, CXCR4 has been shown to associate with TCR upon CXCL12 activation [15]. Activation of tyrosine kinases by  $G_{\alpha}$ -subunits has been demonstrated

[17-20] and could represent the mechanism by which CXCR4 activates Lck [21]. We show here that the Src family kinase inhibitor, PP2, abrogated CXCL12-induced tyrosine-phosphorylation of several proteins (Figure 1A, marked with \*), a further indication that Src family kinases act downstream of CXCR4. However, the changes in tyrosine phosphorylation following CXCL12 treatment are modest compared to those of anti-CD3 treatment (data not shown). Furthermore, pre-treatment of Jurkat T cells with CXCL12 prior to stimulation with anti-CD3 attenuated TCR-induced Lck activation (Figure 1B). Similarly, we also observed reduced ZAP-70 phosphorylation in cells pre-stimulated with CXCL12 (Figure 1B). This is in line with a previous report showing reduced TCR-induced phosphorylation of ZAP-70 and LAT in CXCL12-pretreated cells [13] suggesting that post-activation heterologous desensitization is occurring possibly as a result of  $G_{\alpha q}$  sequestration. Consistent with this notion surface expression of CXCR4 was also down after 30 minutes incubation with CXCL12. To address the role of  $G_{\alpha}$ -subunits in controlling the switch between TCR and CXCR4-signaling events, we subjected Jurkat T cells to siRNAs against  $G_{\alpha q}$  or  $G_{\alpha i2}$ . We achieved more than 90% knockdown with these siRNAs as analysed by Western blotting (Fig. 1C). As previously demonstrated [16] TCR-induced Lck Y394 autophosphorylation was reduced in  $G_{\alpha q}$ -knockdown but not  $G_{\alpha i2}$ -knockdown T cells demonstrating that  $G_{\alpha q}$  may directly or indirectly activate Lck (Fig 1C).

### $G_{\alpha q}$ -kd sets the threshold for chemotaxis

The reciprocal regulation between the TCR and chemokine receptors [13,22,23] suggest that the response to a specific chemokine is determined both by the differentiation and the activation state of the responding T cell. This implies that migrating T cells are less responsive to activation through the TCR. The physiological relevance of this switch between migration modus and TCR activation modus may be to ensure that migrating T cells do not get distracted by activation cues until they reach their destination. Conversely, TCR triggered T cells are less responsive to chemotactic gradients to ensure optimal activation. We observed that knockdown of  $G_{\alpha q}$  enhanced basal migration 2-fold (Figure 2A), suggesting that  $G_{\alpha q}$  may set the threshold for directed migration. This supports the findings of Molon et al. [8] who speculated that CXCR4 signaling through  $G_{\alpha q}$  promoted adhesion instead of migration. Accordingly, we saw that knockdown of  $G_{\alpha i2}$  inhibited directed CXCL12-induced migration, while  $G_{\alpha q}$  knockdown had no effect (Figure 2A) confirming the notion that  $G_{\alpha i2}$  is the principal  $G_{\alpha}$ -subunit involved in chemotaxis. The inhibitory effect of  $G_{\alpha i2}$  knockdown could however be partly reversed with simultaneous knockdown of  $G_{\alpha q}$  (Figure 2A). We speculate that the presence of  $G_{\alpha q}$  and absence of  $G_{\alpha i2}$  may result in a combined

**Figure 1** (see legend on next page)

**Figure 1** (see previous page)

**CXCL12-pretreatment attenuates TCR-induced Lck activation.** (A) Jurkat TAg T cells were incubated with or without 10  $\mu$ M PP2 for 30 minutes at 37°C prior to stimulation with CXCL12 (100 ng/ml) for the indicated time-points and stopped with lysis buffer. Cell lysates were subjected to immunoblotting with the indicated antibodies. (B) Jurkat TAg T cells were incubated with 100 ng/ml CXCL12 for 30 minutes at 37°C prior to stimulation with OKT3 (1.5  $\mu$ g/ml) for the indicated time-points and stopped with lysis buffer. Cell lysates were subjected to immunoblotting with the indicated antibodies. Cells were also stained with anti-CXCR4 and surface expression of the receptor was analysed by flow cytometry. (C) Jurkat TAg T cells were transfected with  $G_{\alpha_q}$ -specific siRNA (GNAQ1 I03),  $G_{\alpha_{i2}}$ -specific siRNA (GNAI-2-I050) or control siRNA (GNAQ1 I03 M3). 48 hours post-transfection cells were stimulated with OKT3 (1.5  $\mu$ g/ml) for the indicated time-points and stopped with lysis buffer. Cell lysates were subjected to immunoblotting with the indicated antibodies. All figures are representative of at least 3 independent experiments.

strong inhibitory effect on chemotaxis. Removal of  $G_{\alpha_q}$  will then lead to partial release of the inhibitory effect of  $G_{\alpha_{i2}}$  knockdown alone. Although T cells from  $G_{\alpha_q}^{-/-}$  mice show no migrational defects [7], data from knockout mice are difficult to interpret as compensatory mechanisms may have been established during development. Acute knockdown with siRNA provides an alternative method to examine protein functions. How CXCR4 switches its signaling through  $G_{\alpha_{i2}}$  and  $G_{\alpha_q}$  is unknown, but the level of TCR engagement has been implicated [8,13]. Surface expression of CXCR4 following CXCL12-stimulation was neither affected by knockdown of  $G_{\alpha_q}$  nor  $G_{\alpha_{i2}}$  during a 1-hour time course (Figure 2B, only 0 minutes and 30 minutes shown). The level of surface expression of CD3 on Jurkat Tags has recently been reported [24]. Furthermore, we suggest that neither  $Ca^{2+}$ -elevation nor ERK1/2 phosphorylation are involved in chemotaxis as has been suggested in a previous report [7]. While elevation of intracellular  $Ca^{2+}$  was abrogated in the  $G_{\alpha_q}$ -knockdown cells upon CXCR4-stimulation (Figure 2C), it was intact in  $G_{\alpha_{i2}}$ -knockdown cells. The level of ERK1/2 phosphorylation was similar in both  $G_{\alpha_q}$ -knockdown and  $G_{\alpha_{i2}}$ -knockdown Jurkat cells. However, concomitant knockdown of both  $G_{\alpha_q}$  and  $G_{\alpha_{i2}}$  completely attenuated ERK1/2 phosphorylation (Figure 2D), indicating that this is a G-protein dependent event.

#### **The $G_{\alpha_{i2}}$ -kd-signaling pathway dominates the CXCL12-induced migrational response**

To test whether the  $G_{\alpha_{i2}}$ -signaling pathway is the principal pathway activated by CXCR4 we pre-treated cells with the PI3K inhibitor wortmannin prior to incubation with CXCL12. In the presence of wortmannin CXCL12-induced migration was strongly inhibited (Figure 3A vs Figure 2A). Furthermore, in the presence of wortmannin the  $G_{\alpha_q}$ -kd cells displayed an approximately 80% increase in CXCL12-induced migration (Figure 3A). This suggests that the negative regulatory effect of  $G_{\alpha_q}$  on migration is normally not observed when the  $G_{\alpha_{i2}}$  signaling pathway through PI3K is intact, and that a switch from  $G_{\alpha_{i2}}$  to  $G_{\alpha_q}$  is necessary to fully inhibit migration. These observations correlate well with the data showing that co-knockdown

of  $G_{\alpha_q}$  and  $G_{\alpha_{i2}}$  has a smaller inhibitory effect on migration than knockdown of  $G_{\alpha_{i2}}$  alone (Figure 2A). Although the presence of Lck is shown to be necessary for migration [21] activating Lck through the TCR receptor has an inhibitory effect on migration [13]. Consistent with these findings cells transfected with the constitutively active Lck Y505F showed a significant inhibition of migration compared to vector-transfected cells (Figure 3B). Interestingly, the effect of  $G_{\alpha_q}$ -kd on wortmannin-treated T cells in the presence of CXCL12 is reversed when transfected with Lck Y505F indicating that the effect of  $G_{\alpha_q}$  is mediated through Lck (Figure 3C).

#### **$G_{\alpha_q}$ -kd inhibits migration through activation of SHP-1**

Src homology phosphatase-1 (SHP-1) is an Lck-activated tyrosine phosphatase reported to negatively regulate CXCL12-induced migration [25]. As we have recently reported that  $G_{\alpha_q}$  may activate Lck we examined how  $G_{\alpha_q}$  manipulation would affect SHP-1 regulation in migration. Knockdown of  $G_{\alpha_q}$  resulted in decreased tyrosine phosphorylation of SHP-1 compared to control cells (Figure 4A and 4B). This may indicate a role for  $G_{\alpha_q}$  in the activation of SHP-1. Interestingly, increased basal phosphorylation of SHP-1 was observed in  $G_{\alpha_{i2}}$  knockdown cells. This may be due to skewing of the CXCR4 signaling pathway towards  $G_{\alpha_q}$  as there is less  $G_{\alpha_{i2}}$  available. Conversely, knockdown of  $G_{\alpha_q}$  might skew the CXCR4 signaling pathway towards  $G_{\alpha_{i2}}$ . To assess the role of SHP-1 in chemotaxis we transfected Jurkat T cells with the phosphatase-deficient, mutant SHP-1 C453S (c/s) that competes with endogenous SHP-1. Cells transfected with the mutant showed significantly increased basal and CXCL12 induced migration compared to control cells indicating that an Lck- $G_{\alpha_q}$ -SHP-1 pathway may regulate migration (Figure 4C). Migration is probably not exclusively regulated by SHP-1 and other negative regulators of migration activated by  $G_{\alpha_q}$ -kd might exist.

#### **Conclusion**

We have previously shown that knockdown of  $G_{\alpha_q}$  attenuates TCR-induced Lck activation by an unknown mechanism [16]. While  $G_{\alpha_{i2}}$  has a positive role in inducing

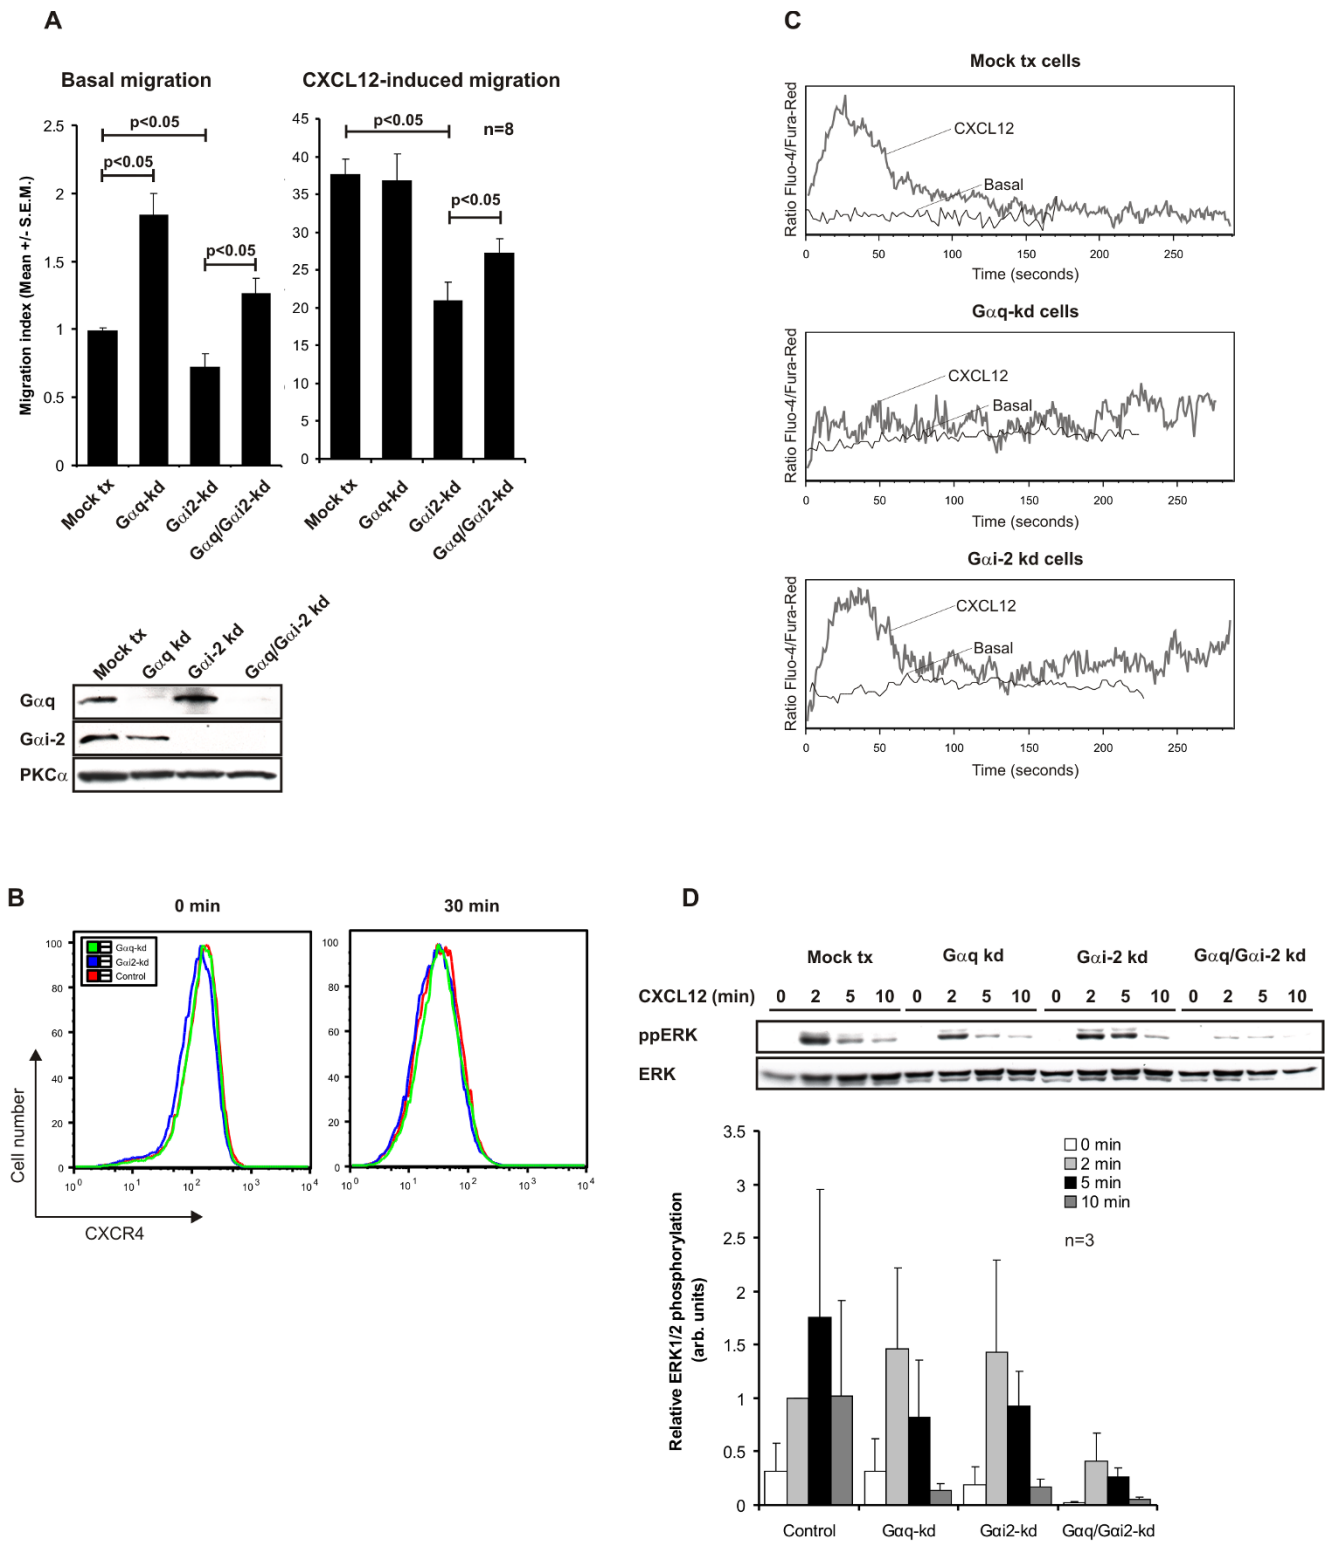

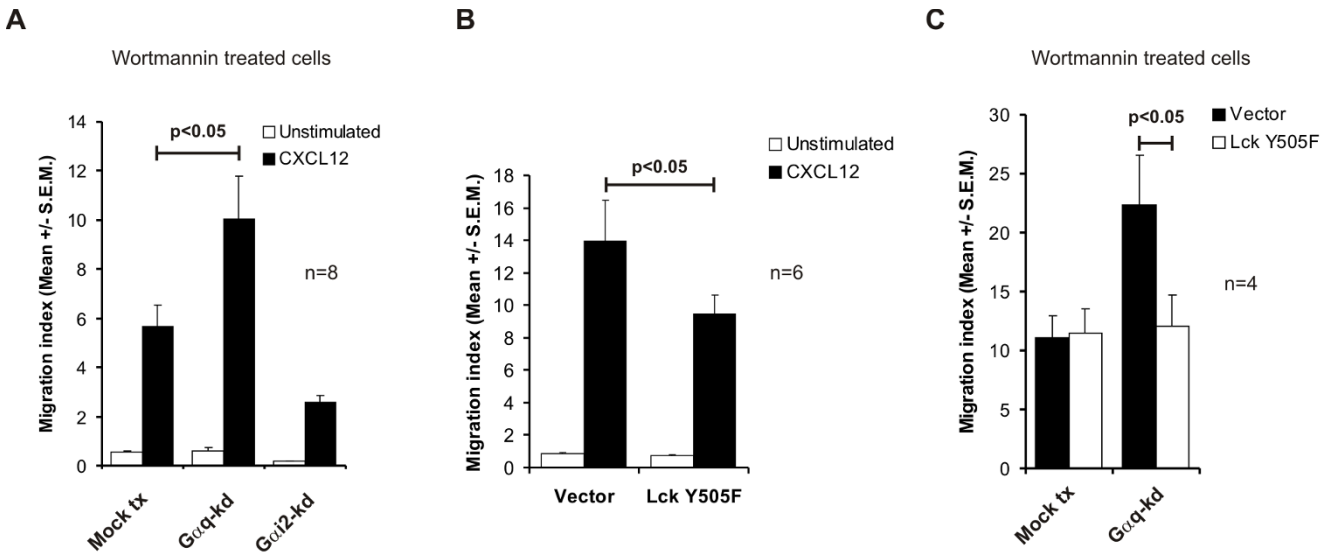

Figure 2 (see legend on next page)

**Figure 2** (see previous page)

**G $\alpha_q$  and G $\alpha_i2$  have opposing roles in chemotaxis.** (A) Jurkat TAg T cells were transfected with G $\alpha_q$ -specific siRNA (GNAQ1103), G $\alpha_i2$ -specific siRNA (GNAI2-1050) or control siRNA (GNAQ1103 M3). 48 hours post-transfection cells were placed in Costar Transwell wells with/without 10 ng/ml CXCL12. After 2 hours incubation the numbers of migrated cells were counted by flow cytometry Migration index was calculated as the number of cells migrating divided by the number of basal migrating mock tx cells (n = 8). (B) Cells were subjected to transfection as in (A). 48 hours post-transfection cells were stimulated with CXCL12 for the indicated time points. Cells were stained with anti-CXCR4 and surface expression of the receptor was analysed by flow cytometry (n = 3). (C) Cells were subjected to transfection as in (A). 48 hours post-transfection cells were stained with Fluo-4 and Fura Red AM and calcium fluxes were measured by flow cytometry. Grey lines indicates CXCL12 stimulated cells, black line unstimulated cells. Representative of 3 independent experiments. (D) Cells were subjected to transfection as in (A). 48 hours post-transfection cells were stimulated with CXCL12 for the indicated time points, lysed and subjected to immunoblot analysis with the indicated antibodies. Levels of immunoreactive protein were quantified by densitometric scanning from 3 independent experiments and normalized against total protein (Mean  $\pm$  S.E.M.).

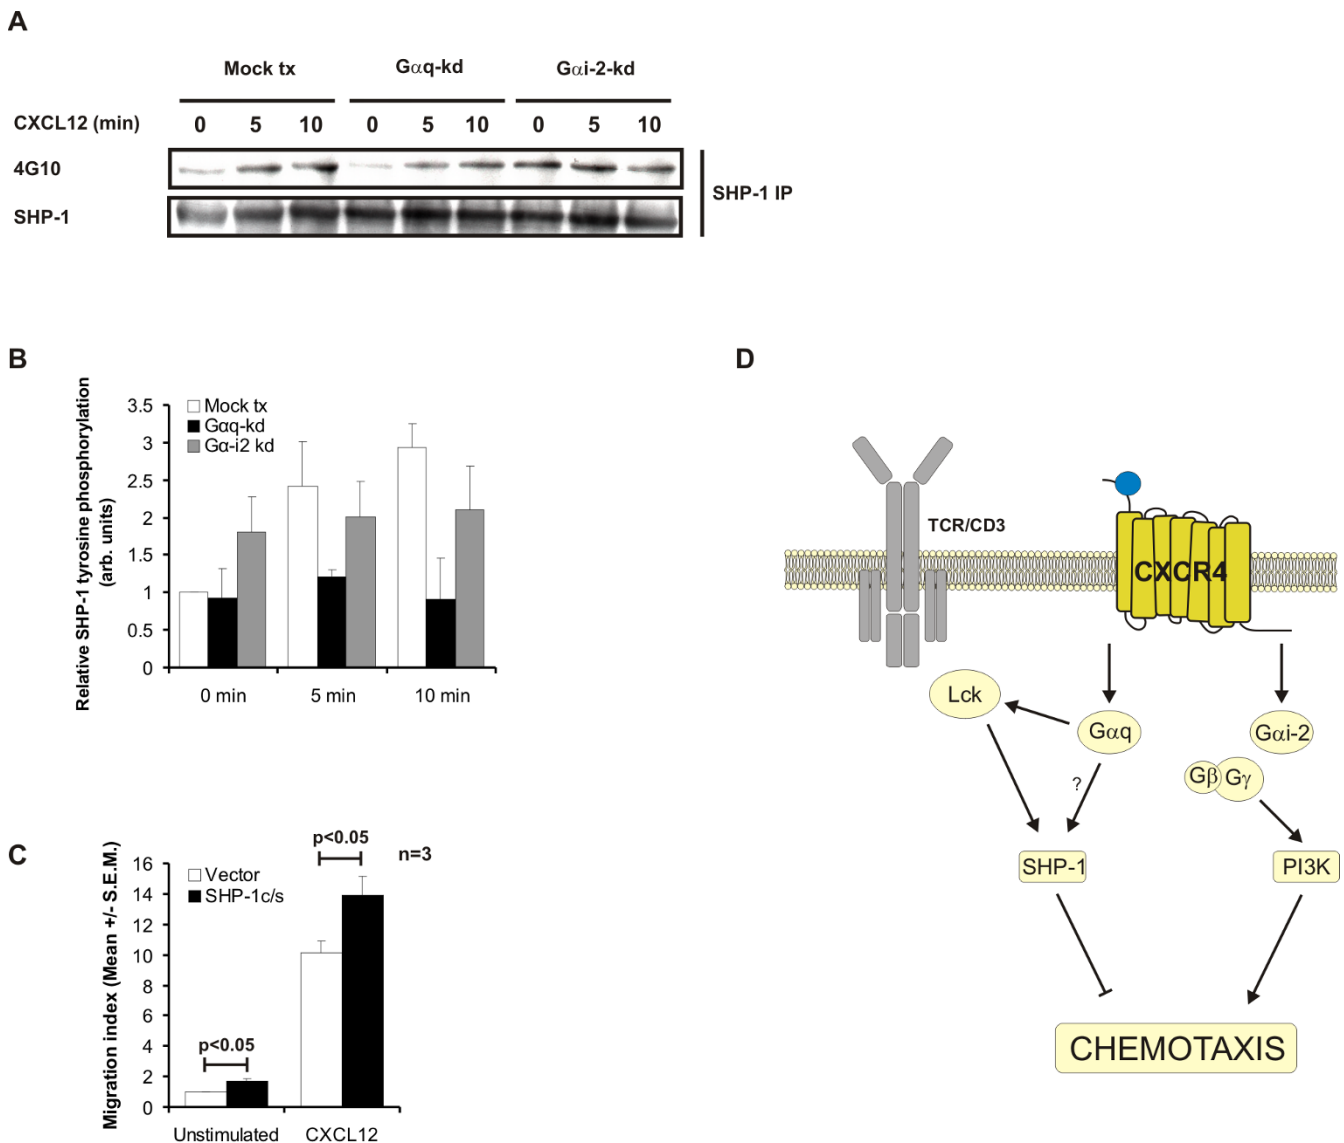

migration, G $\alpha_q$  may have a negative regulatory role by promoting Lck activity resulting in increased SHP-1 activity (Figure 4D). Previous reports have demonstrated a reciprocal regulation between the TCR and chemokine-receptors [13,22,23]. Based on our recent report, an optimal TCR-triggering may require the G $\alpha_q$  signaling pathway as G $\alpha_q$  knockdown attenuates TCR-induced Lck activation [16]. In contrast, G $\alpha_q$  knockdown appears to release migration from tonic inhibition. This is in line with data showing increased proliferation and cytokine-production when chemokine-receptors signal through G $\alpha_q$  [8] sug-

gesting that a switch from G $\alpha_i2$  to G $\alpha_q$  through the chemokine-receptor promotes T cell activation rather than migration. In conclusion, we suggest that G $\alpha_q$  activation strengthens the commitment of T cells to activation through the TCR while G $\alpha_i2$  activation commits the T cell to migration. This might contribute to ensure that T cells migrating towards a site of infection do not get distracted by unnecessary activation cues, while activated T cells are fully committed towards differentiation and proliferation.

**Figure 3**

**CXCL12 stimulation primarily activates G $\alpha_i2$ .** (A) Jurkat TAg T cells were transfected with G-specific siRNA (GNAQ1103), G $\alpha_i2$ -specific siRNA (GNAI2-1050) or control siRNA (GNAQ1103 M3). 48 hours post-transfection cells were pre-treated with Wortmannin for 30 minutes and analyzed for CXCL12 dependent and independent migratory responses. Migration index represents fold migration over basal in control cell wells. (B) Jurkat TAg T cells were transfected with Lck Y505F or empty vector migration was analysed in the absence and presence of CXCL12 (10 ng/ml). Migration index represents fold increase in migration over basal migration in wells with control cells. (C) Cells were subjected to transfection as in (B) pre-treated with Wortmannin as in (A) and migration with CXCL12 was analysed. Migration index represents fold increase in migration over basal migration in wells with control cells.

**Figure 4**

**Migration is inhibited by activation of SHP-1.** (A) Jurkat TAg T cells were transfected with G $\alpha$ q-specific siRNA (GNAQ1103), G $\alpha$ i2-specific siRNA (GNAI-2-1050) or control siRNA (GNAQ1103 M3). 48 hours post-transfection cells were stimulated with CXCL12 for the indicated time periods and lysed in lysis buffer. SHP-1 immunoprecipitation was performed and immune complexes analysed by immunoblotting with the indicated antibodies (n = 3). (B) Immunoblots from 3 independent experiments like in (A) were quantified by densitometric analysis. The graph show mean  $\pm$  S.E.M. (C) Jurkat TAg T cells were transfected with the phosphatase defective SHP-1 c/s (C453S) mutant or empty vector. 24 hours post-transfection cells were placed in Costar Transwell plates with or without CXCL12 (10 ng/ml) and migration analysed as above. Migration index represents fold increase in migration over basal migration in wells with vector tx cells (n = 3). (D) Activation of G $\alpha$ i2 induces migration through a PI3K pathway whereas activation of G $\alpha$ q inhibits migration through an Lck-SHP-1 pathway priming cell for activation through the TCR.

## Authors' contributions

All experiments were designed by JN, MI and KT, and conducted by JI and MI. TB contributed with data analysis and co-wrote paper. All authors read and approved the final manuscript.

## Acknowledgements

We are grateful to Gladys Tjørholm and Jorunn Solheim for technical assistance. This work was supported by grants (to Kjetil Tasken) from the Functional Genomics Programme, The Research Council of Norway, The Norwegian Cancer Society, Novo Nordic Foundation and the European Union (grant no. 037189, thera-cAMP). Publish with **BioMed Central** and every scientist can read your work free of charge

"BioMed Central will be the most significant development for disseminating the results of biomedical research in our lifetime."

Sir Paul Nurse, Cancer Research UK

Your research papers will be:

- available free of charge to the entire biomedical community
- peer reviewed and published immediately upon acceptance
- cited in PubMed and archived on PubMed Central
- yours — you keep the copyright

Submit your manuscript here:  
http://www.biomedcentral.com/info/publishing\_adv.asp
