ABSTRACT

Introduction Approximately 75% of mental disorders emerge before the age of 25 years but less than half receive appropriate treatment. Little is known about the mechanisms underlying the therapeutic change of adolescents in psychotherapy. The ‘European Network of Individualised Psychotherapy Treatment of Young People with Mental Disorders’, funded by the European Cooperation in Science and Technology, will conduct the first systematic review to summarise the existing knowledge on mediators and theories of change in psychotherapy for adolescents.

Method A systematic review will be conducted, conforming to the reporting guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement recommendations. Electronic databases (PubMed and PsycINFO) have been systematically searched on 23 February 2020, for prospective, longitudinal and case-control designs which examine mediators of change. Participants will be adolescents between 10 and 19 years of age who suffer from a mental disorder or psychological difficulties and receive an intervention that aims at preventing, ameliorating and/or treating psychological problems.

Ethics and dissemination Ethical approval is not required for this systematic review as no primary data will be collected. The results will be published in a peer-reviewed journals and at conference presentations and will be shared with stakeholder groups. The whole data set will be offered to other research groups following recommendations of the open science initiative. Databases with the systematic search will be made openly available following open science initiatives.

PROSPERO registration number CRD42020177535.

INTRODUCTION

Adolescents and young adults are a particularly important and vulnerable group with distinct mental health needs. According to Kessler *et al*, 50% of lifetime diagnosable mental health disorders start by the age of

Strengths and limitations of this study

- Review aims at identifying underlying mechanisms of change in the process of psychotherapy for adolescents.
- Reviewers are from a European multidisciplinary researcher network with researchers and clinicians from 30 countries.
- First comprehensive overview of mediators in psychotherapy carried out with adolescents.
- Broad inclusion criteria increase external validity but limits the possibility of causal conclusions including non-randomised controlled trials studies, it is likely not feasible to estimate aggregated effect sizes for the identified mediators.

14, and this number increases to 75% by the age of 25.^{1 2} Ignoring young people’s mental health needs can result in long-lasting adverse developmental outcomes for the individual and society. These include: psychiatric disorders in adulthood, impaired social functioning, difficulties with employment as well as poorer general health outcomes.³

Psychotherapy is effective, efficient and cost-effective, providing long-term impacts which are not possible with psychopharmacological treatment alone.^{4–6} There is strong evidence on the general effectiveness of psychotherapy for treating mental disorders in adolescents,^{7 8} and a wealth of psychotherapy treatment modalities are currently being used and researched, with >550 different psychotherapy models that can be applied to young people.⁹ Treatment response is explained by different mechanisms of change and accounted for by a variety of mediators (eg, self-reflection, learning compensatory skills, changing automatic thoughts and so on)

associated with each treatment modality. While various psychotherapy modalities (eg, psychodynamic psychotherapy; cognitive behavioural therapy) have shown equally good treatment outcomes overall, adherence to a specific treatment modality has not shown to significantly impact the outcome in child and adolescent psychotherapy.¹⁰ However, to understand therapeutic change and enhance outcomes, it is necessary to identify treatment processes or characteristics within the therapist, the adolescent, parent or family that facilitate successful therapeutic change and isolate those that are redundant and can be dismissed.⁹ Thus, research on underlying specific mechanisms of change across treatment modalities and settings is essential to optimising treatment.

An important first step towards examination of mechanisms of change in psychotherapy is the identification of mediators. While moderators (eg, gender, age) serve to clarify what kind of treatment is adequate for a specific person under certain circumstances, mechanisms of change define causal relationships between therapeutic change and psychological interventions. A mechanism of change explains how an intervention translates into a process that leads to an outcome, for example, change in symptoms.¹¹ Thus, a mechanism is an explanatory concept that can be investigated by researching mediators, that is, variables that explain changes statistically. Kazdin has formulated clear criteria on how to assess mediators of psychological treatments¹²:

- ▶ Conduct sufficiently powered randomised clinical trials.
- ▶ Use valid and reliable measures for mediators that are sensitive to change.
- ▶ Apply a process design in which changes of the mediator temporally precede changes in therapeutic outcome and the mediator variable is measured repeatedly.
- ▶ Compare mediators that are theory-driven with non-specific mediators.
- ▶ Apply different dosages to prove that a stronger mediator-change leads to more therapeutic changes.

However, even after 13 years of Kazdin's suggestions on how to assess mechanisms of change in psychotherapy research,¹² there are still an alarming lack of studies, inconclusive results (eg, the treatment of depression in adults)¹³ and very little research on change mechanisms for the treatment of adolescents.^{14 15} Cuijpers *et al* conclude that despite >70 years of systematic psychotherapy research, we have no empirically validated mechanisms of change in adult psychotherapy.¹⁶ The current systematic review will be the first to summarise the existing knowledge on mediators and theories of change in psychotherapy for adolescents.

To address these challenges related to mediators and measures of the mechanisms of change and therapies' efficacy in children and adolescents, besides other activities, the European Cooperation in Science and Technology (COST) funded a 4-year programme named 'European Network of Individualised Psychotherapy Treatment of

Young People with Mental Disorders' (TREATme) (www.treat-me.eu) that serves as a European multidisciplinary researcher network with researchers and clinicians from 30 countries. TREATme will review the academic research relating to mechanisms of change in patients aged between 10 and 30 years receiving psychological treatments. For the current review, the part of the collected data set concerning adolescents only will be used. The aim is to provide an overview of existing research on psychological factors that mediate psychotherapeutic change in adolescents. We will conduct a narrative synthesis of all studies available up to 2020. The objectives of this review are the following:

1. To identify which mediators and theories of change have been studied in psychotherapy with adolescents.
2. To identify if there are adolescence-specific, disorder-specific or treatment-specific mediators.
3. To critically evaluate the methodological approach of the current research data available on mediators in psychotherapy for adolescents.

In order to obtain a comprehensive overview of the field of psychotherapy for adolescents, we will include various forms of psychotherapy and quantitative research designs. We will select all studies including a statistical test of mediation (eg, Baron and Kenny or more advanced methods)¹⁷ and will summarise study characteristics and results. We will discuss the extent to which these studies meet the most important requirements for mediator research that were mentioned earlier. Furthermore, we will relate mediators to the respective theories of change and describe which mediators successfully explain therapeutic change. Ultimately, this review can contribute to the challenging process of identifying underlying mechanisms of change in the process of psychotherapy for adolescents.

METHOD

The review follows the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols.¹⁸ This article is based on work from the COST Action TREATme aiming to improve knowledge and understanding of psychotherapeutic interventions in young people. The patient/population, intervention, comparison and outcomes (PICO) model was used to define the research question.

Eligibility criteria

Studies from any geographical location, written in English, available as full-text and published from inception onwards until 23 February 2020 that meet criteria, will be included in the review. Grey literature such as theses, dissertations or conference proceedings will also be included.

Types of studies

Due to a lack of studies fulfilling all criteria for mediator research, we decided to include a broad range of study

types. Studies will be selected if they include statistical analysis of mediators in psychotherapy. This comprises (a) empirical quantitative studies following prospective, longitudinal and case-control designs, (b) terms related to or describing mediators and (c) a psychosocial intervention and/or psychotherapeutic intervention or treatment for primary/secondary prevention.

Types of participants

WHO defines adolescents as individuals between 10 and 19 years of age,¹⁹ which was the age group selected for our inclusion criteria. These participants would have a mental disorder (eg, depression, eating disorders) or psychological difficulties (eg, binge drinking) and receive a psychotherapeutic intervention, including primary and secondary prevention programmes. All comparators will be included as we will be investigating mediators in all treatments and not the efficacy of one treatment over another.

Types of interventions

Studies will be included if they report an intervention aimed at preventing, ameliorating and/or treating psychological problems of adolescents by using psychosocial mechanisms and strategies in any setting (ie, individual, family, group, inpatients, eMental health and so on). These interventions should not be primarily biological or physiological. Examples of interventions include all branches or types of psychotherapy: psychodynamic, integrative, systemic, cognitive-based or cognitive-behavioural, interpersonal, humanistic (such as emotion-focused, supportive, motivational interviewing), psychoeducation and third-wave approaches (such as mindfulness-based therapies).

Search strategy

The search strategy includes terms relating to or describing the intervention. These terms have been combined with the Cochrane MEDLINE filter for controlled trials of interventions and were adapted for PsycINFO.²⁰ Studies published from inception to 23 February 2020 have been sought. The search string can be found in the online supplemental file 1. The search was performed on 23 February 2020.

Data extraction

Study selection will be carried out by a group of 20 experienced researchers divided into 10 pairs who will independently assess the eligibility of studies retrieved using the search strategy in two phases. The first phase comprises the screening of the titles and/or abstracts of studies that potentially meet the inclusion criteria outlined above. In the second phase, each pair of reviewers will evaluate the full text of these potentially eligible studies to see if they meet the inclusion criteria. Disagreements will be discussed by the pair, and a third reviewer will be involved if consensus cannot be reached. Finally, a fourth independent reviewer will perform an additional quality control check by assessing the eligibility of every fifth excluded

study. Disagreements at this stage will be solved through discussion with the original review pair.

Data records will be managed with the support of Microsoft Excel.²¹ A standardised form will be used to extract the information for the review. Extracted information will include: study setting; study population, participant demographics and baseline characteristics; details of the intervention and control conditions; study methodology; outcomes and times of measurement; assessed mediators; type of mediation analysis and information for assessment of the risk of bias. Two review authors will extract information independently; discrepancies will be identified and resolved through discussion or with a third author when necessary.

Critical appraisal

Although no standard form for evaluating mediation studies has been established, studies will be checked against general criteria for identifying mediators of psychosocial interventions in research, such as summarised by Kazdin¹² and Lemmens *et al.*¹³

Data synthesis

We will provide a narrative synthesis of the findings from the included studies, with a focus on the categories of mediators that have been tested, types of psychosocial interventions that have been investigated and mental disorders or psychological difficulties of adolescents that have been treated. It will be discussed if age-specific, disorder-specific or treatment-specific mediators can be identified. The age-specific mediators will be identified by comparing results with mediators identified by reviews from adult psychotherapy.

Outcomes and prioritisation

The primary outcome will be mediators related to change in mental health problems or disorders in adolescents measured by a validated instrument or tool made for that purpose. Data on the disorder will be categorised into depression, anxiety, substance misuse, externalising problems, severe mental illness (eg, psychosis, bipolar disorder) and others (eg, eating disorders). The therapies will be categorised into: psychodynamic, integrative, systematic, cognitive-based or cognitive-behavioural, interpersonal, humanistic, psychoeducation and third-wave. Mediators and instruments for assessing them will be identified. The statistical analyses for evaluating the effect of mediators will be recorded. Pretreatment and post-treatment scores will be noted, and the differences compared.

Risk of bias in individual studies

The Mixed Methods Appraisal Tool will be used to evaluate the overall study quality using a formal risk of bias assessment.²² This tool permits the appraisal of the methodological quality of five categories of studies: qualitative research, randomised controlled trials, non-randomised studies, quantitative descriptive studies and mixed methods studies.

Patient and public involvement

No patient was involved in planning and conducting the study.

Ethics and dissemination

No ethical approval will be necessary to conduct the review as no additional empirical data will be assessed. Results from the review will be disseminated through a publication in a peer-reviewed open access journal and through scientific communication using the COST Action homepage. The data set that will be established during the search and extractions will be published in an open data repository after the acceptance of the publication of the review order to facilitate access to students, academia and professionals. Additionally, results will be disseminated in conferences, seminars, congresses or symposia.

DISCUSSION

As far as the authors are aware, this is the first systematic review of its kind, assessing mediators of psychotherapeutic changes in adolescents. The findings will inform how much is currently known about such mediators and the practical implications of this knowledge for treatment planning and outcomes. The results will also shed light on how these empirically studied mediators correspond with the theoretically putative mechanisms of change in particular models of intervention. Using qualitative synthesis, we will evaluate and comment on the conclusiveness of age-specific, disorder-specific or treatment-specific mediators and map out the most pressing needs for future research on mediators and mechanisms of change in adolescent psychotherapy. The review will provide a basis for comparing our results with those of systematic reviews in adults, to assess whether there are similar or different mediators in adolescents that explain therapeutic change.

The strengths of this protocol include the gathering of a large multidisciplinary group of international researchers with long-standing accumulated experience in the area that have worked on this topic for 3 years through regular online and face-to-face meetings. Furthermore, the group has consulted international experts in the field to develop the protocol. A structured quality assurance will be carried out, as well as several search updates to ensure the completeness of the data set. The whole data set will be offered to other research groups following the recommendations of the open science initiative.

Limitations of this protocol include the use of broad inclusion criteria to describe the existing knowledge comprehensively and increase external validity, which likely limits the possibility of causal conclusions by also including non-randomised controlled trials. For the same reason, it is likely not feasible to estimate aggregated effect sizes for the identified mediators. Our conclusions on mechanisms of change will only be related to empirical quantitative studies as we have excluded qualitative and theoretical studies. As there is no generally accepted

gold standard for mediation analysis, we expect much variance in the studies, which could lead to our results being inconclusive or inconsistent. Also, we are analysing both subclinical conditions and diagnosable disorders, as well as intervention and prevention studies, which may lead to less consistent or coherent results. We have chosen to do this in order to address the adolescent age group holistically and aim to report the results separately in order to establish independent conclusions. As the rater team consists of a fairly large group, inter-rater bias has to be strictly monitored, and so a fourth independent reviewer will be introduced to perform additional quality control checks.
